SAFE AND SUSTAINABLE WATER RESOURCES RESEARCH PROGRAM

Mississippi River Basin and Gulf Hypoxia Research Overview HTF Coordinating Committee

August 11, 2022

The views expressed in this presentation are those of the author(s) and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

EPA ORD Mississippi River Basin Modeling Efforts: Current Work + Next Steps

Data & Synthesis-Based Approaches

Nutrient Inventories: Links to MRB Water Quality (Lead: Robert Sabo)

Synthesis of BMP Effectiveness in the UMRB (Lead: Yongping Yuan)

Simulation Approaches

Modeling the UMRB: wetlands, nutrients, and more

(Leads: Heather Golden, Grey Evenson, Jay Christensen, Charles Lane)

Multi-media modeling of the MRB & Northern GOM Hypoxia

(Leads: Brandon Jarvis, Yongshan Wan, Yongping Yuan)

Nutrient Inventories: Links to MRB Water Quality

Robert Sabo

Long-Term Mississippi River Trends Expose Shifts in the **River Load Response to Watershed Nutrient Balances**

Input kg km⁻²

Balance kg km⁻²

Issue: Unclear how point and non-point pollution sources have evolved in MR basin and how shifts in pollution sources relate to observed nitrogen and phosphorus loading trends

Approach: Developed highly empirical nutrient inventories to track shifts in urban and agricultural point and non-point sources of pollution. After calculating balances, we related shifts in excess nutrients to observed nutrient loading trends.

Observations from Inventory:

- After ~1980, excess nitrogen and 1. phosphorus left on farm fields largely stabilized and declined, respectively.
- Improvements in nutrient management 2. coincided with ~80% increase in crop removal—good news.

Long-Term Mississippi River Trends Expose Shifts in the River Load Response to Watershed Nutrient Balances

- 1. After 1980, WRTDS flownormalized nitrogen loads declined (blue dots) despite nitrogen balances remaining generally stable (open circles).
- 2. Retention of nitrogen surplus has increased
- 3. After ~2000, WRTDS flownormalized phosphorus loads increased despite declines in phosphorus balances
- 4. Retention of phosphorus has declined in the MS basin

EFFA Latent processes that enhanced nitrogen retention offset further increases in nitrogen loads

- Efficient regression models statistically captured the net effect of lagged nutrient balances and latent processes that altered N retention (blue circles)
- Ran a counter-factual where 1) latent processes did not have a positive effect on nitrogen retention (checkered circles) and
 nutrient balances were returned to lower 1975 levels (open circles)
- If farmers lowered nitrogen balances, combined with the processes that enhanced retention, would have cut N loads to Gulf of Mexico by ~<u>half compared to observed</u> <u>values.</u>

SEPA Why has agricultural surplus not declined in the MS basin?

- Since 1990, Ohio and Illinois farmers have decreased the amount of nitrogen left on fields
- Other parts of the basin had large increases in surplus (e.g., North and South Dakota) or remained stable/slightly increased (lowa)
- Net effect of shifts in agricultural non-point pollution sources resulted in a generally stable or slightly increased surplus trajectories in MS basin

Nitrogen and phosphorus inventories can be leveraged to identify pollution hotspots and offer actionable metrics for stakeholders to improve

- I. Nutrient use efficiency targets of 80-90% are ideal to maintain crop yields, most subbasins are below this target
- 2. Recent USDA CEAP report and our inventory finds farmers are applying manure on top of fertilizer in many areas
- 3. Some area of the country have NUE exceeding 80%, may have to incorporate other BMPs besides ensure better NUE

- Agricultural non-point sources of pollution have largely stabilized for nitrogen and slightly declined for phosphorus
- Latent process altered the retention of nitrogen and phosphorus surplus
 - Nitrogen retention increased, leading to decreased export to the Gulf of Mexico
 - Phosphorus retention decreased, leading to increased export to the Gulf of Mexico
 - We can discuss speculations and further research initiatives later on, your guidance is key to craft products that meet your information needs
- Decreased nitrogen balances, using 4R principles, can lead to decreased nitrogen loads within 5-15 years.
- Certain states have decreased the magnitude of agricultural non-point nitrogen pollution sources but have been offset by recent increases in other states
- Nitrogen and phosphorus inventories can be leveraged to identify pollution hotspots for prioritization efforts and guide the watershed implementation plans.

Synthesis of BMP Effectiveness in the UMRB

Yongping Yuan

€EPA

Effectiveness of Nutrient Management on Nitrate-Nitrogen Loss from Subsurface Drainage

Issue: Excess nutrient fluxes from agricultural fields have been linked to occurrences of lake eutrophication, leading to harmful algae blooms (HABs), and hypoxia in the ocean worldwide such as the Gulf of Mexico.

Approach: Synthesizing available information on nitrogen (N) fertilizer rate, source, application method and timing, along with related drainage water quality and crop yield data.

Impact: Information gained from this research will help: 1) improve nutrient management plans; and 2) inform the selection of ACPs for water quality improvement. Ultimately, it helps the federal government agencies (e.g. USDA-NRCS and EPA-OW) and state government agencies to prioritize their funding for ACPs selection and implementation to achieve water quality goals.

Partners/Clients: Office of Water, Regions 5 and 7

Fertilizer information	Categories	Descriptions									
	Low	< 134 kg N ha ⁻¹									
Fertilizer rate groups	Moderate	134 – 167 kg N ha ⁻¹									
	High	167 – 200 kg N ha-1									
	Very high	> 200 kg N ha ⁻¹									
Fertilizer sources	Inorganic	Urea, $UAN^\dagger,$ and other synthetic fertilizers									
	Organic	Liquid manure & manure									
	Other	No specific sources or no fertilizer applied									
Application methods'	Injected										
	Incorporated										
	Surface applied	Including broadcast applied.									
	Banded										

Response of Crop Yields and NO₃-N Losses to Fertilizer Application Rates

The response of $[NO_3-N]$ (Fig. 1b) to fertilizer rate is different from that of crop yield (Fig. 1a).

a. At low-rate, yields increase as fertilizer rate increases.

b. The change
in concentration
is smaller for lowrate groups (i.e.,
low to medium);
but is higher for
higher rate
groups.

Figure 1. Corn yield (a) and [NO₃-N] (b) for different categories of fertilizer rates.

Impacts of Fertilizer Sources on Crop Yields and NO₃-N Losses

a. Organic fertilizer consistently produced higher corn yields compared to inorganic fertilizer.

b. Organic fertilizer al so produced higher [NO3-N] for all rate groups except the very high group

Figure 2. Comparison of crop yield (a) and [NO₃-N] (b) for different fertilizer sources at different fertilizer rate groups. Only site-years with single applications were included in this study.

Effectiveness of Nutrient Management on Nitrate-Nitrogen Loss from Subsurface Drainage

Take home message(s): Fertilizer rate was found to be the most important factor controlling flow-weighted nitrate-N concentrations; and with higher fertilization rates, corn yields, NO_3 -N loads, and flow-weighted [NO_3 -N] increased. However, the change in corn yield is higher for low-rate groups; while change in concentration is smaller for low-rate groups, but higher for higher rate groups. Furthermore, we did not find significant differences in nitrate-N export among fertilizer application methods or timing.

Modeling the UMRB: wetlands, nutrients, and more

Heather Golden, Grey Evenson, Jay Christensen, Charles Lane

Wetland restoration and dynamic N responses across the UMRB

Issue: Excess nitrogen in the UMRB is transported to streams via runoff and groundwater connections during storm events and baseflow, respectively. *Wetland restoration may help mitigate this surplus nitrogen*.

Approach: We simulated wetland restoration scenarios across the UMRB + characteristics of wetlands and wetland drainage areas and assessed changes in nitrate at 279 subbasins and the UMRB outlet.

Impact: Restoring ~8,000 km² of wetlands will reduce mean annual nitrate loads to the UMRB outlet by 12%. However, these results are dependent on numerous factors (more on these nuances next...)

Partners/Clients: EPA Regions 7 and 5, Upper Mississippi River Basin Association, EPA Office of Water

Nitrate load reductions at subbasin-scales from wetland restoration often, <u>but not always</u>, resulted in load reductions at the UMRB outlet

€PA

Nitrate yields are mostly from tiles in tile-drained subbasins = less wetland N removal

€PA

Characteristics (factors) did not have equal influence on nitrate reductions from wetlands

Wetland restoration and dynamic N responses across the UMRB

Take home message(s): Wetland mitigate surplus nitrogen across the UMRB, yet <u>their effectiveness is dependent several factors</u>: distance to the river basin outlet, wetland catchment-to-area ratios, fraction of tile drainage intercepted by wetlands, and relative abundance of existing wetlands across a subbasin – among others.

Future Research Directions (FY 23-26):

 Potential processes causing lags between BMPs (e.g., wetlands) and changes in water UMRB water quality

- How groundwater and soil N legacy storage + N legacy/climate change interactions mediate wetland restoration effects on N across the UMRB

Multi-media modeling of the MRB & Northern GOM Hypoxia

Brandon Jarvis, Yongshan Wan, Yongping Yuan

See A Multimedia modeling of northern Gulf of Mexico hypoxia

Issue: What will Gulf hypoxia look like in a changing climate? How will nutrient reduction effectiveness be impacted?

Approach: Integration of air, watershed, hydrodynamic, and ecosystem models

- Air: Community Multiscale Air Quality model [CMAQ]
- Watershed: Soil & Water Assessment Tool [SWAT]
- Hydrodynamic: Hybrid Coordinate Ocean Model [HYCOM]
- Ecosystem: Coastal Generalized Ecosystem Model [CGEM]

Impact: Application of a more comprehensive modeling tool to predict climate change effects on hypoxia and inform proactive nutrient management policies

Partners/Clients: EPA Office of Water, Regions 4 and 6, Hypoxia Task Force

Basin-scale Boundary Conditions

Louisiana Shelf

Sepa Multimedia modeling of northern Gulf of Mexico hypoxia

Past Research:

Spatiotemporal Carbon Dynamics

Shifting emphasis from east-west transport to importance of nearshore production

Contiguous Hypoxia

Linked nearshore-offshore hypoxia dynamics for regulatory management between state and federal waters

Model Load Reduction Response

Different model formulations affect estimates of hypoxia response to reduced nutrient loads

Sepa Multimedia modeling of northern Gulf of Mexico hypoxia

Soil & Water Assessment Tool (SWAT) Weather Research and Forecasting (WRF) Community Multiscale Air Quality Modeling System (CMAQ)

Sepa Multimedia modeling of northern Gulf of Mexico hypoxia

Take home message(s): Simulation models are essential tools to inform nutrient management decisions. Models must comprehensively address the multitude of climate change factors to predict future effects on hypoxia.

Future Research Directions (FY 23-26): Development of an integrated modeling approach utilizing national and regional scale models. Emphasis on predicted effects of nutrient reductions and legacy nutrients in the context of climate change.
